Game On! | Week 3 project overview

The problem

Organising a pickleball game means reconciling messages, player availability, travel, court options and booking details. Game On brings that coordination into one shared game, with Ernie preparing a proposal and the organiser retaining control.

The working product

The real application uses FastAPI, a compact HTML/CSS/JavaScript frontend, Neon Managed Better Auth, persistent PostgreSQL groups and votes, MapLibre maps, and an existing bounded LangGraph. The hosted release supports coordination, geographic court comparison, exact-context cached price estimates, organiser approval, assistant briefs and tentative calendar downloads.

How to assess it

Open https://game-on-victoria.vercel.app for the account-based product. Open https://game-on-w3-demo.vercel.app for the separate no-login Agent Brain demonstration. The latter uses fictional players and explicit provider fixtures, but executes the actual bounded graph for every scenario.

What this repository contains

The submission is a clean snapshot of the actual product source through I-069, not a replacement demo. It includes regression tests, essential recorded parser fixtures and these assessment materials. Credentials, account records, internal handoffs and development history are excluded. Private deployment identifiers are replaced with non-working placeholders; security guards remain.

Submission route

Start with README.md, watch demo-video.mp4 and inspect architecture.svg and user-flow.svg. The storyboard provides exact actions and narration. verification.md distinguishes fresh checks, historical evidence and limitations.

Architecture and agentic control

Decision, tool, observation

Ernie reads the authenticated game snapshot, identifies qualifying voted times and selects permitted discovery actions. Tools return structured observations. The graph loops over those results and either proposes a court, searches another eligible time, or requests assistance. Python enforces permissions, revision consistency, action limits and deadlines.

Deterministic does not mean fake execution

The current decision policy is deterministic. LangGraph nodes, tool calls and typed observations genuinely execute; the submission does not claim live LLM inference. An existing guarded model adapter is present in source, but no paid model call is part of this demonstration.

Three demonstrable outcomes

A: suitable fictional court found. B: the first shared time returns no inventory, so a second search uses another already-approved time. C: permitted options are exhausted and human assistance is requested. The Agent Brain view replays completed execution events; it is not streamed internal reasoning. Replay does not call the provider or rerun planning.

Three distinct execution environments

Hosted product: actual account/group data, curated discovery and cached pricing. Hosted demo: isolated fictional state and simulated provider observations, with real graph execution. Local Playwright: supervised real website reading, opt-in and not deployed to Vercel. These paths must not be presented as one autonomous hosted booking service.

Human and security boundaries

The organiser approves a plan before handoff. A changed game revision invalidates stale proposals. Unknown prices remain unknown, and cached observations must match their court/time context. Opening a website, copying instructions or downloading an event does not confirm a booking. No reservation, hold or payment is performed for this submission.

Evidence, verification and limitations

Real local provider evidence

I-069 observed Pickleholic Main Courts for 7 November 2026, 18:30-19:30 Melbourne, returning seven offered courts. Separately approved Next navigation reached Court 3 pricing on 6 November at 01:37:41 UTC: base $50.00, technology fee $1.25, total $51.25, provider player selector 1. Currency code and separate taxes were not exposed. The graph consumed this genuine observation.

Do not overstate that evidence

This is historical evidence, not current availability or a universal rate. Next may create an undocumented temporary hold. Checkout details did not transfer to a fresh browser in earlier investigation. Level Up full live graph acceptance remains blocked by a security challenge. Real-provider unavailable-slot replanning is unverified; B and C demonstrate it with labelled fixtures.

Fresh submission verification

Hosted demo tests passed at 1280 and 375 pixels: repeated A/B/C switching, reset, map loading, comparison, approval, privacy-safe clipboard and tentative calendar. Official booking navigation was intercepted, so it proves URL selection without contacting the venue. Agent Brain event navigation and replay passed with no additional planning network calls. See verification.md for final source-suite results and hosted-account observations.

Release boundary

The live product remains the existing release through I-065, source b85c583. The submission snapshot includes later local I-069 implementation. No deployment or database changes are included in this checkpoint. The demo remains its existing separately hosted implementation.

Next work, not submission claims

Future work would require provider permission and access, validated pricing/availability contracts, hosting/runtime review, explicit booking approval and duplicate prevention. The demonstrated MVP stops at an honest, human-controlled handoff. No additional framework or infrastructure is necessary to assess the current work.
